

Lecture 6 — Solutions

Karpikova Alina

Exercise 1. Let $\Omega = (0, \pi) \times (0, \pi)$ and define on $L^2(\Omega)$ the operator A as

$$Af = \Delta f, \quad D(A) := \{f \in C^2(\Omega) : \text{the support of } f \text{ is compact}\}.$$

Show that A is dissipative and its closure generates a contraction semigroup.

Proof. The support of f is a compact, so we have

$$f(0, \cdot) = f(\pi, \cdot) = f(\cdot, 0) = f(\cdot, \pi) = 0.$$

Then

$$\begin{aligned} \langle Af, f \rangle &= \int_0^\pi \int_0^\pi (\partial_{xx}f(x, y) + \partial_{yy}f(x, y)) f(x, y) dx dy \\ &= \int_0^\pi \left(\int_0^\pi (\partial_{xx}f(x, y)) f(x, y) dx \right) dy + \int_0^\pi \left(\int_0^\pi (\partial_{yy}f(x, y)) f(x, y) dy \right) dx \\ &= \int_0^\pi \left((\partial_x f(x, y)) f(x, y) \Big|_0^\pi - \int_0^\pi (\partial_x f(x, y))^2 dx \right) dy \\ &\quad + \int_0^\pi \left((\partial_y f(x, y)) f(x, y) \Big|_0^\pi - \int_0^\pi (\partial_y f(x, y))^2 dy \right) dx \\ &= - \int_0^\pi \left(\int_0^\pi (\partial_x f(x, y))^2 dx \right) dy - \int_0^\pi \left(\int_0^\pi (\partial_y f(x, y))^2 dy \right) dx \\ &= - \int_0^\pi \int_0^\pi \left((\partial_x f(x, y))^2 + (\partial_y f(x, y))^2 \right) dx dy \leq 0. \end{aligned}$$

By Proposition 6.5. we have that A is dissipative.

Consider $f \in C^2(\Omega)$. By Theorem 6.3. it is sufficient to prove that $\text{ran}(\lambda - A)$

is dense in X for some (hence all) $\lambda > 0$. Then closure of A generates a contraction semigroup. Consider $(\lambda - A)f$. If $f \in C^2(\Omega)$, then $(\lambda - A)f$ is linear combination of functions in $C^2(\Omega)$ and $C(\Omega)$. This space is dense in $L^2(\Omega)$. Then by theorem 6.3 we have that A generates a contraction semigroup.

Consider an arbitrary orthogonal system.

Let $f(x, y) = \alpha_{nm} \sin nx \sin my$ is orthonormal basis in $L^2(\Omega)$. Let

$$(\lambda - A)f = (\lambda + \alpha_{nm}(n^2 + m^2)) \sin nx \sin my, \quad m, n \in \mathbb{Z}.$$

This is orthogonal (orthonormal) system where $\sin nx \sin my$ is orthonormal basis. Then this system is dense in $L^2(\Omega)$. Then $\text{ran}(\lambda - A)$ is dense in $L^2(\Omega)$.

Exercise 4. Suppose that A generates a contraction semigroup and

$B : D(B) \rightarrow X$ satisfies $D(A) \subseteq D(B)$, and has the following property:

There is $a \in [0, \frac{1}{2})$ and $b > 0$ such that

$$\|Bx\| \leq a\|Ax\| + b\|x\| \quad \text{for all } x \in D(A).$$

Prove that for large $\lambda > 0$ one has $\|BR(\lambda, A)\| < 1$.

Proof. Let $x = (\lambda I - A)^{-1}y$ or $x = R(\lambda, A)y$ and we have $D(A) \subseteq D(B)$.

Consider following inequality

$$\begin{aligned} \|Bx\| &= \|B(\lambda I - A)^{-1}y\| \leq a\|A(\lambda I - A)^{-1}y\| + b\|(\lambda I - A)^{-1}y\| \leq \\ &a\|(A - \lambda I + \lambda I)(\lambda I - A)^{-1}y\| + b\|(\lambda I - A)^{-1}y\| \leq a\|y - \lambda(\lambda I - A)^{-1}y\| + \frac{b}{\lambda}\|y\|. \end{aligned}$$

Proposition 6.2. implies the following inequality: $b\|(\lambda I - A)^{-1}y\| \leq \frac{b}{\lambda}\|y\|$.

Consider the norm

$$\begin{aligned} \|\lambda(\lambda I - A)^{-1}y\| &= \left\| \lambda \int_0^\infty T(t)e^{-\lambda t} dt y \right\| \\ &\leq \lambda \int_0^\infty \|T(t)\| e^{-\lambda t} dt \|y\| \leq \lambda \frac{\|y\|}{\lambda} = \|y\|. \end{aligned}$$

Inequality holds because A generates a contraction semigroup. Then let $a < \frac{1}{2}$ and for large $\lambda > 0$ from previous inequality we have

$$\|BR(\lambda, A)y\| < \frac{1}{2}\|y\| + \frac{b}{\lambda}\|y\| \leq \frac{1}{2}\|y\| + \frac{1}{2}\|y\| = \|y\|.$$

Thus, $\|BR(\lambda, A)\| < 1$.

Exercise 5. Let $X = C_0(\mathbb{R})$ and $Af = f'' + f'$ with

$$D(A) = \{f \in C^2(\mathbb{R}) \cap X : f'' + f' \in X\}.$$

Show that it generates a contraction semigroup.

Proof. Let $A = A_0 + B$, $A_0f = f''$, $Bf = f'$ with

$$D(A_0) = \{f \in C^2(\mathbb{R}) \cap X : f'' \in X\} \text{ and}$$

$$D(B) = \{f \in C^1(\mathbb{R}) \cap X : f' \in X\}.$$

Note that A_0 generates Gaussian semigroup

$$(T_0(t)f)(x) := \frac{1}{\sqrt{4\pi t}} \int_{\mathbb{R}} f(y) e^{-\frac{(x-y)^2}{4t}} dy$$

which is a contraction (*see Prop.2.17.*) and B generates shift semigroup

$(S(t)f)(s) = f(t + s)$. Then A generates semigroup T , defined as

$$(T(t)f)(x) = (T_0(t)S(t)f)(x) = \frac{1}{\sqrt{4\pi t}} \int_{\mathbb{R}} f(y + t) e^{-\frac{(x-y)^2}{4t}} dy.$$

T is a contraction because T_0 is a contraction and by replacement $\tau = y + t$ we obtain that T is Gaussian semigroup. Thus, A generates a contraction semigroup.
